# Introduction

- ① 'An approach to portfolio optimization with time series forecasting algorithms and machine learning techniques' by Jyotirmayee Behera and Pankaj Kumar.
- ② Motivation: optimal asset selection and portfolio construction
- ③ Challenge: selecting an efficient model (balancing model limitations) to model stock price fluctuations

# Table of Contents

## ARIMA(p,d,q) Model

$$\phi(L)(1 - L)^d y_t = \theta(L)\varepsilon_t \quad (1)$$

$$\phi(L) = 1 - \phi_1 L - \phi_2 L^2 - \dots - \phi_p L^p \quad (2)$$

$$\theta(L) = 1 - \theta_1 L - \theta_2 L^2 - \dots - \theta_p L^p \quad (3)$$

$$\varepsilon_t \sim WN(0, \sigma^2)$$

- Linear combination of past values and white noise, differenced to stationarity
- Limitation: cannot capture non-linear patterns in time series data

# Model Selection

## GARCH(p,q) Model

$$h_t = \alpha_0 + \sum_{i=1}^q \alpha_i \varepsilon_{t-i}^2 + \sum_{j=1}^p \beta_j h_{t-j} \quad (4)$$

$$\varepsilon_t = \sqrt{h_t} v_t, \quad v_t \sim IID(0, 1) \quad (5)$$

- Captures volatility clustering, forecasts time-varying volatility
- Limitation: limited forecast horizon (assume deterministic and symmetric volatility, and normally distributed errors)

## ARIMA+GARCH Model

- Effective in modeling volatility, but lacks in capturing complex price dynamics

# Model Selection

## Neural Network Models

- types: ANN, RNN, MLP, LSTM
- Limitations: data hungry, high tuning and computational complexity

## ARIMA+Neural Network Models

- Efficient in time series modeling / forecasting, but not suitable for financial applications

# Model Selection

## SVM Model

- Supervised ML algorithm
- High accuracy, effective high-dimensional performance
- Limitations: scalability, requires careful cross-validation, sensitive to extreme outliers

## ARIMA+SVM Model

- Handles non-linearity and more robust to outliers, but not as flexible as neural networks

# Model Selection

## LS-SVM Model

- Enhances speed of solving optimization problems

## ARIMA+LS-SVM Model

- Balances performance, efficiency, and flexibility
- High scalability and accuracy

Chosen model for portfolio optimization!

# Mean-Variance Portfolio Optimization (MVPO)

- Developed by Harry Markowitz, 'Modern Portfolio Theory'
- Maximize expected return (or minimize risk) of a portfolio

Let  $P$  be a portfolio with  $j = 1, \dots, n$  stocks.

$$\min \sigma_P^2 = \sum_{i=1}^n \sum_{j=1}^n \sigma_{ij} w_i w_j$$

$$\text{subject to } \sum_{j=1}^n f_j w_j = f_P,$$

$$\sum_{j=1}^n w_j = 1,$$

where  $\sigma_{ij} = \sigma_i \sigma_j \rho_{ij}$ ,  $0 \leq w_j \leq 1$

Conclusion

## Hybrid Model Approach:

- 1 Employ ARIMA method to fit closing prices ( $y_t$ ) and generate forecasts ( $\hat{f}_t$ )
- 2 Calculate residuals:  $\varepsilon_t = y_t - \hat{f}_t$
- 3 Employ LS-SVM method to fit residual terms ( $\varepsilon_t$ ) and generate error forecasts ( $\hat{\varepsilon}_t$ ), using 8:2 train/test ratio.
- 4 Compute ultimate predictions:  $\hat{y}_t = \hat{f}_t + \hat{\varepsilon}_t$
- 5 Choose stocks with lowest prediction error ( $\min |y_t - \hat{y}_t|$ )
- 6 Integrate MVPO model with chosen high-performing stocks to achieve most efficient portfolio

# Statistical Testing

**Friedman Test** - used to assess statistically significant differences in prediction accuracy.

$H_0$ : mean performance metrics of all models are identical

$H_1$ : significant disparities in the models' average performances

**Results:** reject  $H_0$ . At least one model's performance differs significantly from the others.

# Statistical Testing

**Nemenyi Test** - post-hoc test for pairwise comparison of models after a global statistical test (such as the Friedman test) has rejected the null hypothesis of similar performance.

## Results:

Nemenyi post-hoc test  $p$ -values for MAE.

	ARIMA	SVM	LS-SVM	ARIMA+SVM	ARIMA+LS-SVM

Conclusion

- 1 Employ [SVM, LS-SVM, ARIMA, ARIMA+SVM, ARIMA+LS-SVM]+MVPO to represent MVPO models incorporating predicted stocks from each SVM, LS-SVM, ARIMA, ARIMA+SVM, ARIMA+LS-SVM model, respectively.
- 2 Determine optimal portfolio for  $f_P = 0.0003, 0.0005, 0.0007, 0.0009, 0.0011, 0.0013, 0.0014$ .
- 3 Compute variance, standard deviation, and Sharpe Ratio for each portfolio.

$$SR = \max\{SR(P)\}, \text{ where } SR(P) = \frac{f_P}{\sigma_P}$$

# Existing Literature

## ERC Model:

- 'Equally-weighted Risk Contribution' portfolio by Maillard et al. (2009-2010)
- ensures each asset contributes same marginal risk
- maximizes diversification without relying on expected returns
- limitations: may overweight low-volatility assets

## Minimax Portfolio Optimization Model

- by Young et al. (1998)
- maximizes worst-case return (equivalently, minimizes maximum loss) across past observation periods
- limitations: overly conservative if past worst cases are outliers, ignores variance and potential upside returns

Conclusion

- ARIMA+LS-SVM demonstrates superior stock price prediction
- ARIMA+LS-SVM+MVPO achieves superior risk-return efficiency, higher returns, lower variance and standard deviation, higher Sharpe ratio, and improved portfolio cumulative returns → outperforms alternatives
- potential applications in algorithmic trading and risk management
- future research could incorporate additional factors and more diverse stock market datasets

# Conclusion

# Thank you!
